9 mm.; ovipositor, 9 mm.; width third femora at width, 4 mm.

Type in U. S. Nat. Mus.

One female, Mesilla Park, New Mexico, August 12, 1898 (Cos.).

The species is very distinct from brevipes. The latter is less variegated in color and the calcarea of the posterior tibia is not so complete. In the two of the third tibia proportionally much longer than those of brevipes, and

FIG. 1a.

the third tibiae are straight on the lower side instead of slightly curved as in brevipes. The third femora of phrixocenoides are apically about one-third as broad as the basal portion, while in brevipes the apical width is more than one-half the basal width.

Figure 1 shows the type specimen of phrixocenoides and figure 1a represents third leg much enlarged.

A new Mayfly of the genus Caenis.

By Nathan Banks.

The genus Caenis is one of the most distinct in the Ephemeroidea. Its species, however, being small, are little known. Hagen recorded two species from the Eastern States, and recently Dr. Needham has described a third. I have a new species from the West, described below, and another form from Florida. Dr. Needham has figured the wings of the three species; however, I do not find that there is as much difference in the venation as would appear from his figures. He shows the wing of C. krimai with fewer cross-veins than C. dirhnuma, and both without anal cross-veins, yet in all the specimens...
of this genus that I have seen, the anal cross-veins are present as well as all those shown for C. diminuta. The difference is in the distinctness of these veins, the anal, and sometimes some of the others, only can be seen when held against the light; moreover, there is variation in this distinctness, and in the position of these cross-veins, while additional cross-veins are sometimes present. In his figure of C. allecta Dr. Needham shows the last fork of the radial forks arising from the lower instead of the upper branch; this is not mentioned in the description, but is different from all specimens seen by me.

My new species differs chiefly by its broader wings, and I shall therefore call it

**C. latipennis n. sp.**

Thorax pale, shining brown, paler on sides; abdomen dull brown above, paler beneath; legs pale, tips of femora darker; setae pale, faintly annulate with brown; wings whitish, the subcosta and radius very dark and prominent; the anterior cross-veins to median fairly distinct, those behind very faint. The marginal hairs of wing are very short near tip, but longer behind toward base. Tibia of male plainly more than twice as long as femur. Anal stylets long, and sharp-pointed as figured for *C. diminuta.*

Expanse 8 to 9 mm.

Several specimens from Pullman, Washington, June.
